Grasshopper Monitoring and Control in British Columbia

December, 2015

Of the estimated 60 species of grasshoppers found in British Columbia, two species are of economic importance in most outbreak situations. These are the clear-winged grasshopper, *Camnula pellucida*, and the migratory grasshopper, *Melanoplus sanguinipes*. Other species, such as the two-striped grasshopper, *Melanoplus bivittatus*, and the redlegged grasshopper, *Melanoplus femurrubrum*, have also been recorded causing problems in B.C. Rangelands are under constant threat from grasshopper outbreaks during which grasshoppers compete with livestock for available forage. It is important that grasshopper outbreaks be detected early and any control actions be taken at the correct time and on an economic basis.

Biology of Grasshoppers

Economic species of grasshoppers overwinter in pods of 20 to 30 eggs laid in the soil the previous year. These pods are very resistant to cold and drying. Depending on site and weather, the eggs hatch during May and June and the young hoppers (nymphs) begin feeding and growing. Over the next 4 to 6 weeks they will pass through five stages (called instars) at which times they shed their skins in order to grow. Fully winged adult hoppers emerge from the final instar and begin mating about a week later. Only adult hoppers are able to fly and reproduce. During outbreaks when suitable forage is scarce, adults will swarm over large areas in search of food. Swarming will cease when females begin laying eggs. Each female can lay two to three egg pods per week until she dies due to freezing temperatures.

hillsides and in weedy areas, especially where the sod has been disturbed and vegetation is sparse, such as stubble fields, road allowances, overgrazed and weedy pastures.

Weather conditions play a very important role in the survival of hoppers and development and intensity of outbreaks. Outbreaks are usually preceded by 2 to 3 years of above average temperatures during the summers and falls. Warm, snow-free falls allow hoppers more time to feed and lay eggs and allow more complete egg development for faster and more even hatching the next spring. A late spring and cool summer delays nymphal development so that fewer adults are available to lay eggs. Cool, wet conditions during hatch will increase nymphal mortality; in August and September, such conditions will slow down egg laying. An early fall will cause many females to die before laying their full complement of eggs.

Damage and Action Thresholds

Grasshoppers feed on a wide variety of grassy and broadleaf plants, and if preferred hosts are lacking, will attack trees and shrubs. The amount of damage or crop loss is directly related to the number of grasshoppers present. Clear-winged grasshoppers prefer sedges and grasses, including cereals. Migratory grasshoppers and related species feed on both grassy and broadleaf plants, hence their preference for weedy areas.

Research has found that over the season, 12 to 24 grasshoppers per square metre in bluegrass

ECOLOGICAL NOTES ON ORTHOPTERA (S. STR.) IN BRITISH COLUMBIA

V. R. VICKERY AND B. NAGY*

ABSTRACT

Collections and observations were made of the grasshoppers of the semi-arid Okanagan Valley of British Columbia, during August and September, 1969. The habitats, frequency and local distribution of 37 species are discussed, based on 40 collecting sites.

J. ENTOMOL. SOC. BRIT. COLUMBIA 109, DECEMBER 2012

Updated checklist of the Orthoptera of British Columbia.

JAMES W. MISKELLY¹

ABSTRACT

Since the last publication of a checklist of the Orthoptera of British Columbia, much has been learned about the group. New information has come from a variety of web-based resources as well as new collections. An updated checklist is presented, listing 104 resident species in the province. Two of these species are represented by two subspecies in BC. Eight species have been added since the last list was published, including newly discovered native species and newly established non-native species. Records of six species have been found to be based on misidentified specimens and these species have been deleted from the checklist. An additional 15 species are considered hypothetical and may one day be confirmed to occur in BC.

CAUSES OF RANGE DEPLETION

There must be a reason for the outbreaks of grasshoppers that have occurred in the interior sections of British Columbia, during the past forty years. It is possible that in the years previous to 1889, periods of extreme prevalence took place of which we have no record. Even granting that these periods did occur, no permanent or material damage to the range grasses took place until twenty to thirty years ago, as is evidenced by the excellent stands of bunch grass over the entire "dry belt," recollection of which is still present in the minds of those who have been resident in the districts for a long time (fig. 5). It is not necessary however, to rely on hearsay to realize that where the numbers of stock to the area available for ranging is in judicious proportion or where rotations of grazing grounds are practised, grasshoppers do not, or even cannot, permanently injure the range grasses.

Not much is known about grasshoppers in BC before 1889, but in Alberta, Saskatchewan, and the USA, it was a periodic emergency, caused by a species that is now extinct.

GRASSHOPPERS OF BRITISH COLUMBIA.

By R.C.Treherne and E.R.Buckell.

that in 1919 the red-legged grasshopper, *Melanoplus femur-rubrum* (De Geer), occurred in great numbers on the Matsqui prairie. Garden produce was attacked on this occasion and oats were cut for hay owing to the damage being caused.

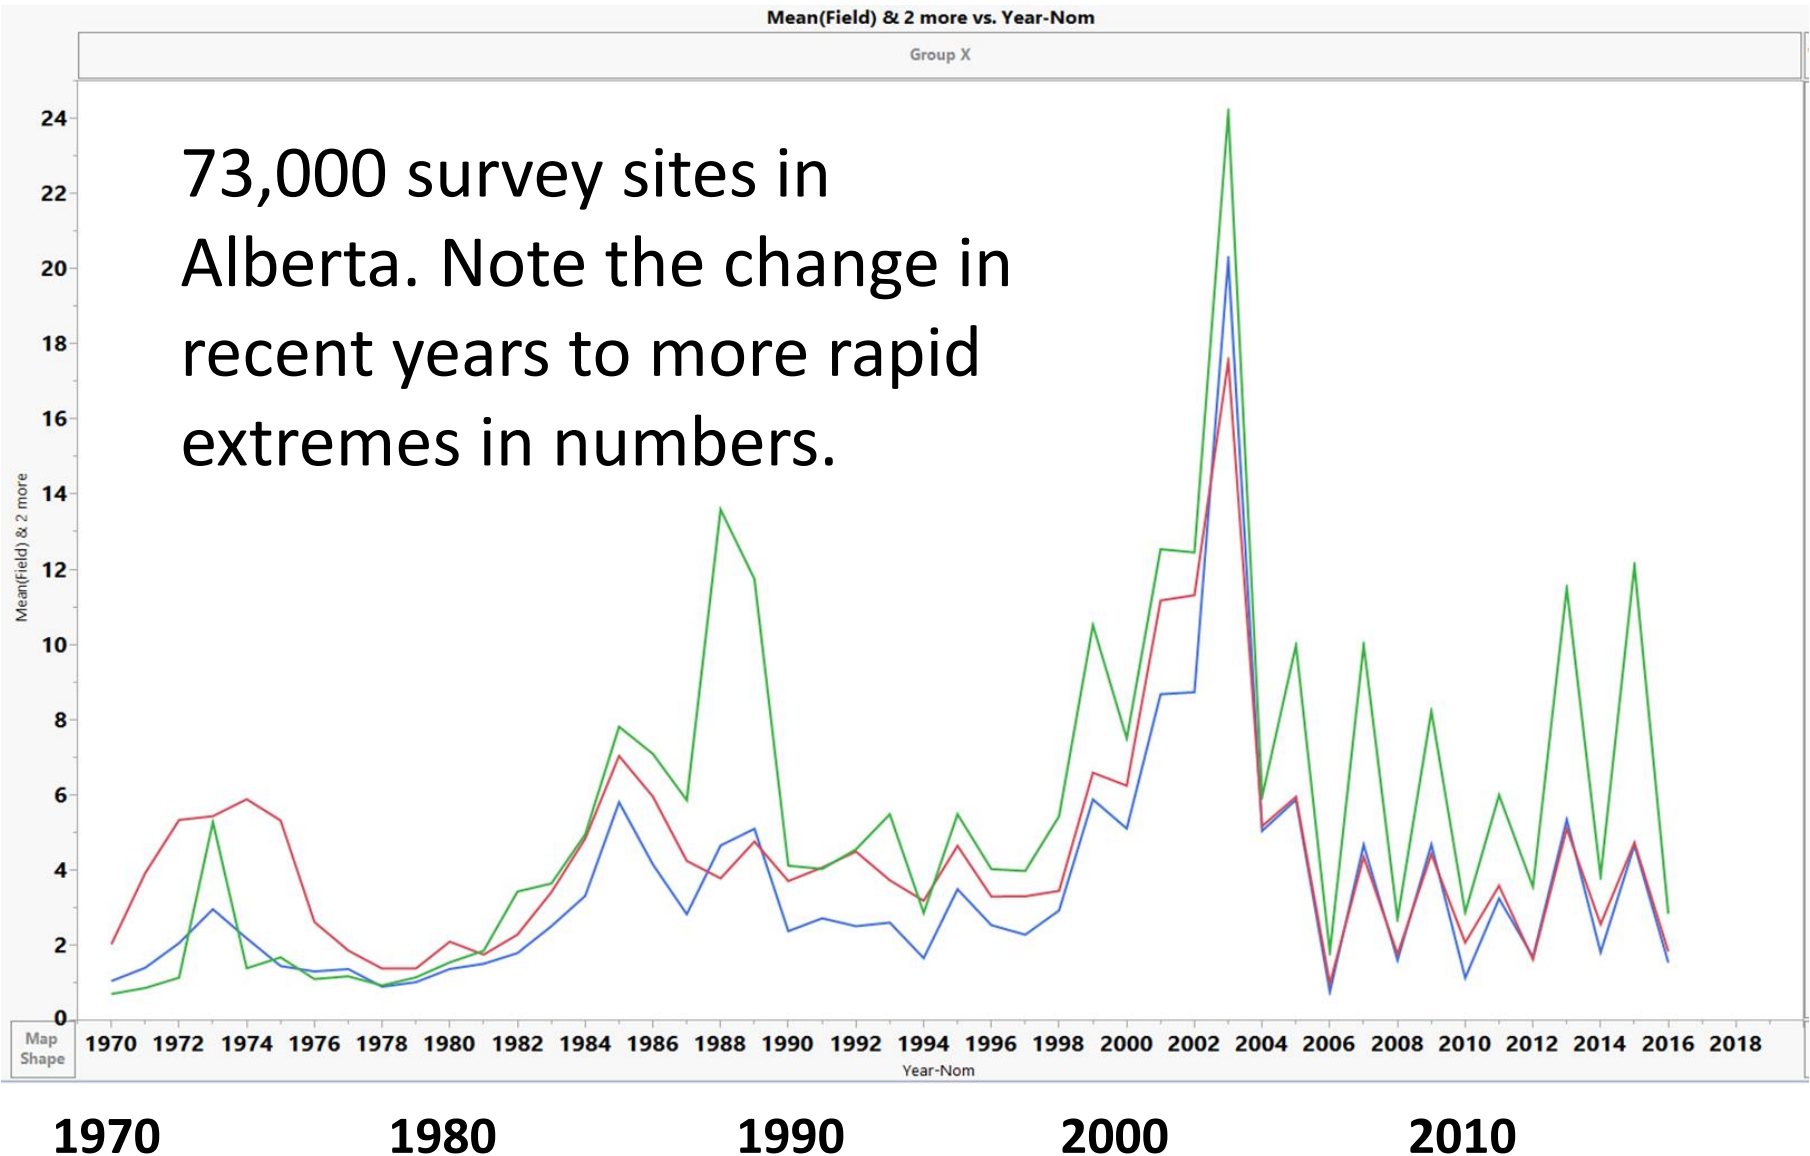

Fig. 4—Graph showing hypothetically the heights of the grasshopper outbreaks in the Okanagan and Nicola valleys respectively during the years indicated.

(...outbreaks in BC were severe in the 1930s, esp. 1944)

Mechanical methods

B. Water-tight trays to fit into bottom of frame to hold the water and coal oil. (Original.)

in use the trays, fig. 4B, are filled with about an inch of water and one-half inch of coal oil, into which the locusts fall after striking the back or sides of the hopperdozer. The appliance is drawn by two horses, one on each end, see fig. 5. It is especially useful in pastures where there is some risk in using poisoned-baits.

FIG. 5. Hopperdozer in use. (Original.)

pulleys about 12 inches to 16 inches in diameter can be used with truck wheels and fastened on the outside of the wheel. A tightener pulley with spring tension to keep the chain or drive belt taut is essential. This tightener pulley can serve as a clutch to start or stop the bait spreader.

The drive for the types which are constructed from the wheels and rear axle assembly of discarded automobiles is already provided for. When the propeller shaft is placed in a vertical position it supplies an excellent drive shaft for the spreader table.

Because of the difference in gear ratio in different automobiles, it is sometimes necessary to use additional gears or other means to increase the speed of the spreader table and thus throw the bait the desired distance. This applies especially when the auto trailer type is drawn by horses and also when the required spread of bait cannot be obtained unless the machine is hauled faster than the rate of about 15 miles per hour, which is the maximum suitable for travel on baiting areas.

FIVE TYPES OF SPREADERS

The following five types are described:—

- (a) End gate type.
- (b) Auto trailer type.
- (c) Combine straw spreader type.
- (d) Cone-hopper wagon or truck type.
- (e) Truck trailer type.

END GATE TYPE

Essential parts consist of: A specially constructed end gate on which is mounted a 14- by 22-inch oil drum, or any 25-gallon drum; a binder reel gear assembly with an automobile radiator fan for spreading the bait. The machine

Grasshopper Monitoring and Control in British Columbia

December, 2015

Of the estimated 60 species of grasshoppers found in British Columbia, two species are of economic importance in most outbreak situations. These are the clear-winged grasshopper, *Camnula pellucida*, and the migratory grasshopper, *Melanoplus sanguinipes*. Other species, such as the two-striped grasshopper, *Melanoplus bivittatus*, and the redlegged grasshopper, *Melanoplus femurrubrum*, have also been recorded causing problems in B.C. Rangelands are under constant threat from grasshopper outbreaks during which grasshoppers compete with livestock for available forage. It is important that grasshopper outbreaks be detected early and any control actions be taken at the correct time and on an economic basis.

Biology of Grasshoppers

Economic species of grasshoppers overwinter in pods of 20 to 30 eggs laid in the soil the previous year. These pods are very resistant to cold and drying. Depending on site and weather, the eggs hatch during May and June and the young hoppers (nymphs) begin feeding and growing. Over the next 4 to 6 weeks they will pass through five stages

hillsides and in weedy areas, especially where the sod has been disturbed and vegetation is sparse, such as stubble fields, road allowances, over-grazed and weedy pastures.

Weather conditions play a very important role in the survival of hoppers and development and intensity of outbreaks. Outbreaks are usually preceded by 2 to 3 years of above average temperatures during the summers and falls. Warm, snow-free falls allow hoppers more time to feed and lay eggs and allow more complete egg development for faster and more even hatching the next spring. A late spring and cool summer delays nymphal development so that fewer adults are available to lay eggs. Cool, wet conditions during hatch will increase nymphal mortality; in August and September, such conditions will slow down egg laying. An early fall will cause many females to die before laying their full complement of eggs.

Damage and Action Thresholds

Grasshoppers feed on a wide variety of grassy and broadleaf plants, and if preferred hosts are lacking,

Scudderia pistillata

*Most of what people consider to be grasshoppers
of British Columbia and Alberta agricultural land...*

Acrididae, short-horned grasshoppers.

130 species in Canada; three main subfamilies:

spur-throated - protruding spine on throat area

slant-faced - front profile oblique; sing

band-winged - hind wings often colored

**Separate taxonomic families: crickets,
katydids and bush crickets**

Some **BASIC RULES** of thumb:

- ✓ Any grasshopper flying before June 1 is not a pest.
- ✓ Crop pest grasshoppers hatch in late May and early June, are brown or black, and always have tiny triangular wing buds, not large wings that can be folded back when examined closely.
- ✓ Any grasshopper with coloured hindwings (under the forewings that serve as covers) visible in flight is not a pest.
- ✓ Any grasshopper that sings, calls, clacks, clatters or makes any other song is not a pest.
- ✓ Any grasshopper that inhabits a crop on a warm day without feeding on the vegetation may be a temporary resident that is moving to more preferred vegetation.
- ✓ Grasshoppers that remain in rangeland, headlands, or other grassland without moving into crops are likely to be species that do not damage crops (monitoring during warm weather will allow this to be determined).

Grasshoppers

short-horned grasshoppers

spur-throated – protruding spine on throat (some pests)

slant-faced - front profile oblique; sing (no pests)

band-winged - hind wings often colored (no pests)

katydids and bush crickets (no pests)

Pest of pasture grass and cereal crops

Clear-winged Grasshopper is a species in the band-winged family of grasshoppers, but their hind wings (visible in flight) are clear. Pest of cereals and grass, not broadleaf crops.

The Clear-winged Grasshopper will likely increase in B.C. grasslands under warm, dry conditions. It flies to new sites to breed.

BC AGRICULTURE & FOOD

Cariboo Region

BC Agriculture & Climate Change
Regional Adaptation Strategies series

Changing pests, diseases & invasive species

AS TEMPERATURES WARM, particularly winter temperatures, the range and prevalence of pests, diseases and invasive species is anticipated to shift. These changes may involve conditions that enable existing problem species to increase and new species to move into the region.

The Cariboo region has been significantly impacted by Mountain Pine Beetle outbreaks, in part because of a lack of extremely cold winter temperatures to control beetle populations. Some existing pests that producers are concerned may become more problematic include: wasps (for apiculture), fire ants, mildews, root maggots, cutworms, blights, wilts, and the grey tortrix moth in alfalfa. More challenging from the perspective of producers is the potential for the introduction of species into areas where they have not previously existed.

Critical to managing changes in populations and ranges of economically significant species (those that cause extensive damage to crops or harm to livestock) is monitoring what is occurring on the ground. Existing resources around monitoring and management in the Cariboo region include the Cariboo Chilcotin Coast Invasive Plant Committee (CCCIPC), and the Cariboo Regional District's Invasive Plants Program.³¹ The CCCIPC has conducted a number of monitoring and management pilots that provide a strong base for future programs.

The strategies in this section work toward the *goal* of:

- *Minimizing and managing agricultural impacts of changing pest, diseases, and invasive species distribution and prevalence*

Relevant Climate Change Impacts

- Increasing temperatures, growing degree-days/heat units, growing season length
- Warmer winter temperatures
- Increasing spring precipitation and extreme rain events
- Drier summer conditions

and lay eggs and allow more complete egg
development for faster and more even hatching
the next spring. A late spring and cool summer
delays nymphal development so that fewer adults
are available to lay eggs. Cool, wet conditions
during hatch will increase nymphal mortality; in
August and September, such conditions will slow
down egg laying. An early fall will cause many
females to die before laying their full complement
of eggs.

Damage and Action Thresholds

Grasshoppers feed on a wide variety of grassy and
broadleaf plants, and if preferred hosts are lacking,

winter in
previous
old and
the eggs
ng hoppers
ver the
five stages
their skins

Table 1. Nymphs and Adults per Square Metre

Rating	Field	Roadside	Control Action
Normal	0 - 3	0 - 6	not required
Light	4 - 6	7 - 12	usually not required
Moderate	7 - 12	13 - 24	may be required
Severe	13+	25+	required

For rangeland, use the values under Roadside to
establish infestation rating. The quality and
quantity of the forage (AUM value), cost of
alternative or supplemental forage sources and
cost of control (product and application) should be
considered when deciding whether control is
justified.

**Again, damage will be
apparent.**

Life cycle and survey.

Eggs are laid about an inch into the soil, in late summer.

They are typically the size of large grains of rice.

A coarse screen can be used to check for eggpods. Pods are about the size and shape of macaroni, and have a foam plug at the end of the eggs. Eggs are the size of rice.

Pest grasshoppers hatch between May 25 (warm spring) and June 15 (cool spring).

Underdeveloped

Partly developed

Ready to hatch

Eggs can be soaked in dilute bleach and examined. Eyes indicate that development is under way. A darker hopper embryo indicates that the eggs are close to hatching.

One-day-old:
two-striped grasshopper
(dan.johnson@uleth.ca)

Newly hatched grasshoppers (end of May, and early June) are very small, but have a hopper appearance.

Not grasshoppers

**Counts in the fall are for the survey.
Spring notes and collections help to
improve it.**

Count the approximate
number per square
meter (about 10 sq. ft.)

Observations by the public are very useful: location and year of large numbers

Appears to be a female lesser migratory grasshopper,
Melanoplus sanguinipes.

Red-legged grasshopper, *Melanoplus femurrubrum*, would
be more yellow underneath and have less of a barred
pattern on the hind femur.

(-Dan)

Katydids and Bush Crickets are not pests in Canada. Any singing grasshopper is not a pest.

On grass, this small species may be confused with the less migratory grasshopper

Little spur-throated grasshopper

Clear-winged Grasshopper sometimes congregate

Turin – Enchant, AB, June 7, 2001

Review of tips...

NOT A PEST:

A grasshopper that does any of these.

- flies before June.**
- has wings highly visible in flight (red, yellow, orange or black).**
- sings, calls, clacks, clatters or makes other similar sounds, either in flight or on the ground.**
- inhabits a crop on a warm day without feeding.**

Natural enemies

**Flies,
crickets,
diseases
of insects.**

Melanoplus infantilis Scudder
Little spur-throated grasshopper

Does not feed on cereal crops significantly.
Feeds lightly on pasture grass.

***Metarhizium anisopliae* (Deuteromycotina: Hyphomycetes)**

Cultural Control Methods

- **crop and cultivar selection** (resistance to feeding)
- **early seeding**
- **timing control measures** (early warning)
- **weed control** (can reduce egg-laying and survival)
- **trap strips.** Grasshoppers drawn to the trap strips can be economically killed with insecticide.
- Natural enemies of grasshoppers may reduce numbers. These can include beetles, fungal diseases, predators, and parasites.
